(54) A stable and active nickel catalyst for carbon dioxide reforming of methane to synthesis gas

(57) This invention refers to a novel nickel-based catalyst which exhibits excellent activity and stability for carbon dioxide reforming of natural gas (methane) to synthesis gas. The catalyst consists of nickel crystallites in contact with La_2O_3 carrier or in the form of nickel supported on La_2O_3 carrier or in the form of nickel on La_2O_3 particles dispersed on a conventional carrier such as $\gamma\text{-Al}_2\text{O}_3$. The stable and active surface of $\text{Ni/La}_2\text{O}_3$ is formed, following two hours of the reaction of carbon dioxide reforming of methane at temperatures higher

than 600°C. In contrast to conventional nickel-based catalysts, e.g. $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$, the new $\text{Ni/La}_2\text{O}_3$ catalysts (at the stable state) are not prone to coking in the temperature range of 550-850°C, exhibiting excellent stability. Near complete conversion of methane and carbon dioxide, and around 100% selectivity to carbon monoxide and hydrogen are achieved over the $\text{Ni/La}_2\text{O}_3$ catalysts under stoichiometric conditions at temperatures in the neighbourhood of 800°C and a superficial contact time of ca. 0.02 seconds.

Fig.3

EP 0 692 451 A1

Description

The invention relates to a novel nickel-based catalyst with excellent stability and activity for carbon dioxide reforming of natural gas (methane) to synthesis gas.

This catalyst can be used in large-scale industrial conversion reactors of any type for the production of synthesis gas (CO and H₂) from natural gas or any other source of methane. It is well known that huge reservoirs of natural gas, consisting of primarily methane, exist. This raw material of very low value can be converted to valuable products over said catalyst, such as synthesis gas, which can subsequently be easily converted to other products such as gasoline, methanol, etc.

Technical Field

This invention refers to a novel nickel-based catalyst which exhibits excellent activity and stability for carbon dioxide reforming of natural gas (methane) to synthesis gas. The catalyst consists of nickel crystallites in contact with La₂O₃ carrier or in the form of nickel supported on La₂O₃ carrier or in the form of nickel on La₂O₃ particles dispersed on a conventional carrier such as γ -Al₂O₃. The stable and active surface of Ni/La₂O₃ is formed, following two hours of the reaction of carbon dioxide reforming of methane at temperatures higher than 600°C. In contrast to conventional nickel-based catalysts, e.g. Ni/ γ -Al₂O₃, the new Ni/La₂O₃ catalysts (at the stable state) are not prone to coking in the temperature range of 550-850°C, exhibiting excellent stability. Near complete conversion of methane and carbon dioxide, and around 100% selectivity to carbon monoxide and hydrogen are achieved over the Ni/La₂O₃ catalysts under stoichiometric conditions at temperatures in the neighbourhood of 800°C and a superficial contact time of ca. 0.02 seconds.

Background of the Invention

Steam reforming of methane is used extensively in industry to form synthesis gas. However, the synthesis gas produced by steam reforming of methane has a hydrogen-to-carbon monoxide ratio of 3 which is undesirable for the Fischer-Tropsch synthesis network, since excess hydrogen suppresses chain growth and decreases selectivity to higher hydrocarbons [D.L. Trimm, Catal. Rev. Sci. Eng. 16 (1977) 155]. Comparably, carbon dioxide reforming of methane is favourable since it produces a synthesis gas with a lower hydrogen-to carbon monoxide ratio. In addition, the carbon dioxide reforming of methane reaction has very important environmental implications because both methane and carbon dioxide are greenhouse gases which may be converted into valuable feedstock. No established industrial technology for carbon dioxide reforming of methane to synthesis gas exists, in spite of the potentially attractive incentives for a large number of applications. A major problem inhibiting the materialization of this process is catalyst deactivation by carbon deposition via Boudouard reaction ($2\text{CO} \rightarrow \text{C} + \text{CO}_2$) and/or methane cracking ($\text{CH}_4 \rightarrow \text{C} + 2\text{H}_2$), which are favourable under reaction conditions [J.T. Richardson and S.A. Paripatyadar, Appl. Catal. 61 (1990) 293; A.T. Ashcroft, A.K. Cheetham, M.C.H. Green, P.D.F. Vernon, Nature 352 (1991) 225; T. Sodesawa, A. Dobashi and F. Nozaki, Reaction Kinetics Catal. Lett. 12 (1979) 107].

During the past decades, the process of carbon dioxide reforming of methane has received attention, and the effort has been focused on development of catalysts which show high activity towards the conversion of CH₄/CO₂ to synthesis gas, and are resistant to coking, displaying stable long-term operation. Numerous supported metal catalysts have been tested for the carbon dioxide reforming process. Among them, nickel-based catalysts [T. Sodesawa, A. Dobashi and F. Nozaki, Reaction Kinetics Catal. Lett. 12 (1979) 107; A.M. Gadalla and B. Bower, Chem. Eng. Sci. 43 (1988) 3049; A.M. Gadalla and M.E. Sommer, Chem. Eng. Sci. 44 (1989) 2825] and supported noble metal catalysts (Rh, Ru, Ir, Pd and Pt) [J.T. Richardson and S.A. Paripatyadar, above; A.T. Ashcroft, A.K. Cheetham, M.C.H. Green, P.D.F. Vernon, above; A. Erdohelyi, J. Cserenyi and F. Solymosi, J. Catal. 141 (1993) 287; J.R. Rostrup-Nielsen and J.-H. Bak Hasen, J. Catal. 144 (1993) 38.] give promising catalytic performance in terms of methane conversion and selectivity to synthesis gas. The catalysts based on noble metals are reported to be less sensitive to coking than are the nickel-based catalysts [A.T. Ashcroft, A.K. Cheetham, M.C.H. Green, P.D.F. Vernon, above; L. Basini, M. Marchionna, S. Rossini and D. Sanfilippo, UK E patent Application No. 2240284 A1]. However, considering the aspects of high cost and limited availability of noble metals, it is more practical and more economical, from the industrial standpoint, to develop an improved nickel-based catalyst which is resistant to carbon deposition, and exhibits stable operation for a long period of time.

Arakawa et al. [T. Arakawa, M. Oka and Fr. Demande, Patents No. FR-2228102, NL-7302403, US-3849087, DE-2308161] used Ni/ γ -Al₂O₃ catalyst to obtain synthesis gas from a mixture of methane, carbon dioxide and water. They found that the catalyst deactivates rapidly by formation of carbon on the catalyst surface, but addition of vanadium (5-10 wt%) to the catalyst can decrease, to a certain extent, the formation of coke. Rapid catalyst deactivation due to strong carbon deposition on supported Ni catalysts was also observed by Chubb [T.A. Chubb, Sol Energy 24 (1980) 341], Velenyi et al. [L.J. Velenyi, C. Paparizos and F.A. Pesa, European Patent Appl. No. 84273 A2] and Rostrup-Nielsen [J.R. Rostrup-Nielsen, Stud. Surf. Sci. Catal. 36 (1988) 73]. It was claimed that catalyst deactivation is due to coke formation within the pores of the catalyst, which leads to the breakup of the catalyst particles. Carbon dioxide reforming of methane was

studied in detail by Gadalla et al. [A.M. Gadalla and B.Bower, above, and A.M. Gadalla and M.E. Sommer, above] over Ni supported on different carriers. They found that no carbon deposition was obtained when reaction temperature as high as 940°C and a CO_2/CH_4 ratio ≥ 2 were applied. However, such reaction conditions are not practical for industrial operation. Recently, Yamazaki et al [O. Yamazaki, T. Nozaki, K. Omata and K. Fujimoto, Chem. Lett. (1992) 1953] obtained carbon-free operation of carbon-dioxide reforming of methane at 850°C by adding CaO to Ni/MgO catalyst. However, significant reduction in reaction rate was registered due to the presence of a strong basic component. Also, no data on the selectivity to carbon monoxide and hydrogen were reported.

Increasing reaction temperature (above 700°C) helps to alleviate coke formation on metal surfaces. However, sintering of nickel particles, as well as possible undesirable solid state reactions between nickel and the support material, are expected to become significant as temperature approaches 850°C, which would eventually lead to decrease of catalytic activity. High reaction temperature (>850°C) also results in difficulties in industrial operation. A thermodynamic study of the carbon dioxide reforming of methane reaction reveals that near complete conversion of methane and carbon dioxide, and about 100% selectivity to carbon monoxide and hydrogen (using a feed of $\text{CH}_4/\text{CO}_2=1/1$, and 1 bar total pressure) are attainable at temperatures in the neighbourhood of 800°C [A.M.Gadalla and B.Bower, above, and A.M.Gadalla and M.E.Sommer, above]. Therefore it is of industrial interest to develop an improved nickel-based catalyst which is capable of producing complete conversion of CH_4/CO_2 to synthesis gas at temperatures $\leq 800^\circ\text{C}$, while displaying stable long-term operation.

Brief description of the invention

In this invention, a novel nickel-based catalyst which exhibits excellent activity and stability for carbon dioxide reforming of natural gas (methane) to synthesis gas is described. The catalyst consists of nickel in contact with La_2O_3 and it could be in the form of nickel supported on La_2O_3 carrier or in the form of nickel on La_2O_3 particles dispersed on a conventional carrier such as $\gamma\text{-Al}_2\text{O}_3$. This catalyst can be prepared by any means known to practitioners of this art, including the technique of wet-impregnation of lanthanum oxide with an aqueous solution of a nickel compound (e.g. nickel nitrate). The surface structure of Ni/ La_2O_3 catalyst experiences a significant alteration upon exposing to CH_4/CO_2 mixture at reaction temperatures, as indicated by the observation of significant increase in the reaction rate during the initial 2 - 5 hours of reaction time. After this, the surface composition of the Ni/ La_2O_3 catalyst reaches equilibrium under the working reaction conditions. The resulting catalyst surface then becomes excellently stable, exhibiting no deactivation during 100 hours of reaction time or more. Conversion of the reactants close to those expected at thermodynamic equilibrium are obtained over this catalyst at a contact time as low as 0.02 seconds (steam reforming of methane reactors over the commercial catalyst typically have superficial contact times of the order of 1 second [M.V. Twigg, ed., Catalyst Handbook, Wolfe, London, 1989]). Upon the application of this novel Ni-based catalyst (i.e. Ni/ La_2O_3) the materialisation of carbon dioxide reforming of methane to synthesis gas at a larger scale may be practically considered.

Brief description of the drawings

Figure 1 shows the alteration of the reaction rate as a function of the time on stream over Ni/ La_2O_3 , Ni/ $\gamma\text{-Al}_2\text{O}_3$ and Ni/CaO catalysts under the following reaction conditions: $P_{\text{CH}_4}=0.2$ bar, $P_{\text{tot}}=1.0$ bar, $\text{CH}_4/\text{CO}_2=1$, $T=1023$ K, $W/F=2 \times 10^{-3}$ g.s/ml.

Figure 2 shows the alteration of the reaction rate as a function of the time on stream over a 17 wt% Ni/ La_2O_3 catalyst at reaction temperatures of 550, 650 and 750°C under the following reaction conditions: $P_{\text{CH}_4}=0.2$ bar, $P_{\text{tot}}=1.0$ bar, $\text{CH}_4/\text{CO}_2=1$, $W/F=2 \times 10^{-3}$ g.s/ml.

Figure 3 shows the alteration of the conversion of CO_2 and CH_4 , and the selectivity to CO and H_2 as a function of time on stream over a 17 wt% Ni/ La_2O_3 catalyst under the following reaction conditions: $P_{\text{CH}_4}=0.2$ bar, $P_{\text{tot}}=0.1$ bar, $\text{CH}_4/\text{CO}_2=1$, $T=1023$ K, $W/F=2 \times 10^{-2}$ g.s/ml.

Figure 4 shows the influence of Ni metal loading on the reaction rate and the stability of Ni/ La_2O_3 catalyst under the following reaction conditions: $P_{\text{CH}_4}=0.2$ bar, $P_{\text{tot}}=1.0$ bar, $\text{CH}_4/\text{CO}_2=1$, $T=1023$ K, $W/F=2 \times 10^{-3}$ g.s/ml.

Figure 5 shows the influence of contact time on the conversion of the reaction over a 17 wt% Ni/ La_2O_3 catalyst. The dotted lines correspond to the values expected at thermodynamic equilibrium. Reaction conditions: $P_{\text{CH}_4}=0.2$ bar, $P_{\text{tot}}=1.0$ bar, $\text{CH}_4/\text{CO}_2=1$, $T=1023$ K.

Figure 6 shows the influence of reaction temperature on the conversion of the reaction over a 17 wt% Ni/ La_2O_3 catalyst at a contact time of 0.06 g.s/ml. The dotted lines correspond to those expected at thermodynamic equilibrium. Reaction conditions: $P_{\text{CH}_4}=0.2$ bar, $P_{\text{tot}}=1.0$ bar, $\text{CH}_4/\text{CO}_2=1$.

Figure 7 shows the effect of treatments on the reaction rate over a 17 wt% Ni/ La_2O_3 catalyst, following the establishment of the stable surface state. The reaction conditions were the following: $P_{\text{CH}_4}=0.2$ bar, $P_{\text{tot}}=1.0$ bar, $\text{CH}_4/\text{CO}_2=1$, $T=1023$ K, $W/F=2 \times 10^{-3}$ g.s/ml.

Detailed description of specific embodiments

In this invention, a novel nickel-based catalyst exhibiting excellent activity and stability for carbon dioxide reforming of methane to synthesis gas is described. The catalysts were prepared by the wet-impregnation method, using $\text{Ni}(\text{NO}_3)_2$ as the metal precursor. Identical catalysts can be prepared using other preparation techniques, known to practitioners of this art, and other metal precursors such as nickel oxide, nickel carbonate, nickel chloride, etc. Three different supports were examined: $\gamma\text{-Al}_2\text{O}_3$, La_2O_3 and CaO . It was found in this work, that the nature of the support has a great effect on the activity and stability of the metal catalysts. While Ni catalysts supported on $\gamma\text{-Al}_2\text{O}_3$ and CaO deactivate continuously with time on stream, the reaction rate over $\text{Ni/La}_2\text{O}_3$ catalyst increases rapidly with time on stream during the initial 2-5 hours of reaction, and then tends to be excellently stable, invariably with time on stream (see Example 3 and Fig. 1). The value of the stable reaction rate over the $\text{Ni/La}_2\text{O}_3$ catalyst is approximately the same as the initial rate over $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$, and is significantly higher than that over Ni/CaO catalyst.

The fresh $\text{Ni/La}_2\text{O}_3$ catalyst consists of Ni particles supported on La_2O_3 , as revealed by XRD analysis (see Example 1). Ni crystallites are known to be sensitive to coking which leads to catalyst deactivation due to blocking of the metal sites. However, the reaction rate over $\text{Ni/La}_2\text{O}_3$ catalyst experiences a significant increase upon exposure to the CH_4/CO_2 mixture. This implies that the structure of Ni supported on La_2O_3 undergoes a significant alteration, induced by the working reaction atmosphere, to form a new surface structure, probably with participation of the species from the gaseous phase. Such a new surface structure exhibits excellent activity towards conversion of CH_4/CO_2 to synthesis gas and possesses exceptional good resistance to coke formation.

A proper nickel loading on La_2O_3 support is an important factor affecting its catalytic performance (reaction rate and stability). It is shown (see Example 6, Fig. 4) that the catalyst with a low metal loading exhibits high reaction rate (using units of $\text{mmol/g}_{\text{metal}}/\text{s}$), as compared to the one with higher metal loading. Since the catalyst with low metal loading presumably has higher metal dispersion, it can be derived that the reaction of carbon dioxide reforming of methane favourably proceeds over the surface containing smaller metal particles. However, the $\text{Ni/La}_2\text{O}_3$ with low metal loading (e.g. 3 wt%) exhibits catalyst deactivation with time on stream, being inferior to the $\text{Ni/La}_2\text{O}_3$ catalyst with high metal loading (e.g. 10 and 17 wt%), over which no detectable catalyst deactivation is observed. By employing a 17 wt% $\text{Ni/La}_2\text{O}_3$ catalyst, conversion and selectivity of the reaction towards CO and H_2 close to those expected at thermodynamic equilibrium are achieved at a superficial contact time as low as 0.02 seconds (see Example 7, Fig. 5). Referring to steam reforming of methane reactors over the commercial catalyst which typically have superficial contact times of the order of 1 second [M.V. Twigg, ed., Catalyst Handbook, Wolfe, London, 1989], the activity of $\text{Ni/La}_2\text{O}_3$ for carbon dioxide reforming of methane is high enough for industrial operation. Complete conversion of methane and carbon dioxide, and near 100% selectivity to CO and H_2 are obtained when reaction temperature is elevated to the neighbourhood of 800°C (see Example 7, Fig. 6). No deactivation is observed over $\text{Ni/La}_2\text{O}_3$ catalyst in the temperature range of $550 - 800^\circ\text{C}$ over 100 hours of reaction. Upon application of this novel nickel-based catalyst, the reaction of carbon dioxide reforming of methane to synthesis gas at a larger scale may now be practically considered.

The present invention, i.e. the $\text{Ni/La}_2\text{O}_3$ catalyst, is a new catalyst and the main differences from all the noble metal catalysts and conventional nickel-based catalysts are the following:

1. The catalysts containing noble metals have been reported to be less prone to coking than are nickel-based catalysts [Richardson and Paripatyadar, above; Ashcroft, Cheetham, Green, Vernon, above; Rostrop-Nielsen and Bak Hasen, above]. However, from the industrial standpoint, the high costs and limited availability of precious metals make noble metal containing catalysts less attractive, as compared to nickel-based catalysts.

2. Noble metal catalysts still deactivate to some extent, particularly when reaction temperatures lower than 700°C are applied [Richardson and Paripatyadar, above; Ashcroft, Cheetham, Green and Vernon, above]. However, the novel $\text{Ni/La}_2\text{O}_3$ catalyst does not deactivate at all within the temperature range from 550 to 800°C (see Example 4 and Fig. 2).

3. Conventional nickel-based catalysts, e.g. $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$, Ni/SiO_2 , Ni/CaO , have been reported to deactivate rapidly with time on stream [Ashcroft, Cheetham, Green and Vernon, above; Sodesawa, Dobashi and Nozaki, above; Chubb, above; Rostrop-Nielsen, Stud. Surf. Sci. Catal. 36 (1988) 73]. This tendency was also verified in the present study for $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$ and Ni/CaO catalysts (see Example 3, Fig. 1). However, no deactivation is observed over the present $\text{Ni/La}_2\text{O}_3$ catalyst. As was already described above, this is due to formation of a new surface structure on $\text{Ni/La}_2\text{O}_3$ catalyst during the first 2 - 5 hours of reaction, which is very different from the Ni crystallites. Also, the reaction rate over this $\text{Ni/La}_2\text{O}_3$ catalyst is significantly higher than that over Ni/CaO , and is approximately the same level as the initial reaction rate over $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$.

4. The nickel catalysts tested by Gadalla et al. (Gadalla and Bower, above; and Gadalla and Sommer, above) are supported on $\gamma\text{-Al}_2\text{O}_3$, $\text{CaO-TiO}_2\text{-Al}_2\text{O}_3$, and MgO carriers. Carbon deposition was not observed only when the following reaction conditions were applied: $T=940^\circ\text{C}$ and $\text{CO}_2/\text{CH}_4 \geq 2$. Under these conditions carbon deposition on surfaces is thermodynamically inhibited. However, as has already been pointed out, significant catalyst sintering

is expected at such a high temperature, which eventually leads to catalyst deactivation. Moreover, such a high reaction temperature, as well as high CO_2/CH_4 ratios, are undesirable for industrial operation.

5 Using strong basic support or adding steam in the feed gas, or partially sulfiding nickel crystallites have been tried in many other previous studies [e.g. Rostrup-Nielsen, above; O.Yamazaki, T.Nozaqi, K.Omata and K.Fujimoto, Chem.Lett.(1992) 1953; and M.F.M.Post, S.T. Sie and E.J.R.Sudhoelter, EP Appl. No. 159759 A2] to alleviate the problem of coking on nickel-based catalysts. However, the consequence is far from satisfactory. Moreover, these approaches usually result in a significant reduction of catalytic activity.

The above discussed differences make the present invention new and innovative.

10 The following working examples represent a more detailed description of the invention and it is understood that this detailed description is given merely by way of illustration and does not limit the extent of the invention as many variations may be made therein without departing from the spirit of this invention.

Example 1

15 This example illustrates the synthesis of nickel catalyst supported on La_2O_3 carrier.

5g of La_2O_3 (Alfa products, 99,9%) were impregnated with an aqueous solution containing the desired amount of nickel nitrate (ultrapure, Alfa Products). The water was evaporated under continuous stirring and the residue was dried at 110°C for 24 hours. The dried residue was then ground and sieved and was heated at 500°C under N_2 flow for 2 hours for complete decomposition of nickel nitrate. After this, the catalyst was reduced at 500°C in H_2 flow for at least 5 hours. The nickel metal loading was 3, 10 or 17 wt%.

20 The $\text{Ni}/\text{La}_2\text{O}_3$ catalyst was characterized by XRD. It was shown that the fresh catalyst consists of metallic Ni crystallites supported on La_2O_3 . The nickel dispersion was measured by H_2 chemisorption at room temperature. Before the measurement, the sample was further reduced at 750°C in H_2 flow for 2 hours. A nickel dispersion of ca. 1% was found for a 17 wt% $\text{Ni}/\text{La}_2\text{O}_3$ catalyst.

Example 2

30 The reaction rates of carbon dioxide reforming of methane over nickel catalysts supported on La_2O_3 , $\gamma\text{-Al}_2\text{O}_3$ and CaO were determined as follows:

35 The CH_4/CO_2 reaction was investigated in the temperature range of $550 - 750^\circ\text{C}$. 10 mg of sample, diluted with 20 mg of $\alpha\text{-Al}_2\text{O}_3$, were charged in a fixed-bed quartz reactor. The reaction feed consisted of 20 vol.% CH_4 , 20 vol.% CO_2 and 60 vol.% He. A total flow rate as high as 300 ml/min was used in order to control the reaction conversion to be much lower than those expected at thermodynamic equilibrium (i.e. the reaction is in the kinetic-controlling regime). Fig. 1 shows the alteration of the reaction rate over $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$, $\text{Ni}/\text{La}_2\text{O}_3$ and Ni/CaO catalysts as a function of time on stream. The rate over $\text{Ni}/\text{La}_2\text{O}_3$ catalyst increases significantly with time on stream during the initial 2 - 5 hours of reaction, and then tends to be invariable with time on stream, indicating $\text{Ni}/\text{La}_2\text{O}_3$ has an excellent stability. The rates over $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$ and Ni/CaO are reduced continuously with time. Although the initial rate over $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$ is much higher than the respective one over Ni/CaO , the deactivation rate over $\gamma\text{-Al}_2\text{O}_3$ is also faster than that of Ni/CaO .

40 The following Table 1 gives the reaction rates obtained over nickel catalysts supported on $\gamma\text{-Al}_2\text{O}_3$, La_2O_3 and CaO carriers at 550, 650 and 750°C . Both reaction rates obtained initially and after 5 hours of the reaction are presented. For $\text{Ni}/\text{La}_2\text{O}_3$ catalyst, the rate after 5 hours of reaction corresponds to the rate at stable level (see Fig.1). It is shown that the initial reaction rate over $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$ is higher than the respective ones over $\text{Ni}/\text{La}_2\text{O}_3$ and Ni/CaO . However, the reaction rate after 5 hours of reaction over $\text{Ni}/\text{La}_2\text{O}_3$ becomes higher than the respective ones over $\text{Ni}/\gamma\text{-Al}_2\text{O}_3$ and

Ni/CaO, indicating Ni/La₂O₃ is superior to Ni/ γ -Al₂O₃ and Ni/CaO in term of reaction rate.

Table 1

Influence of catalyst support on the reaction rate at various temperatures over supported Ni catalyst.				
Catalyst 17 wt% Ni/	State	Reaction Rate (mmol/g.s)		
		550°C	650°C	750°C
La ₂ O ₃	Initial	0.13	0.52	0.95
	After 5h	0.56	1.58	2.18
γ -Al ₂ O ₃	Initial	0.56	1.41	2.20
	After 5h	0.23	0.79	1.48
CaO	Initial	0.10	0.49	1.23
	After 5h	-	0.21	0.72

* Reaction conditions: P_{CH₄}=0.2 bar, P_{tot}=1.0 bar, CH₄/CO₂=1, W/F=2x10⁻³ g.s/ml.

Example 3

In this example, the stability of a 17 wt% Ni/La₂O₃ catalyst was investigated at 550, 650 and 750°C under reaction conditions within which the reaction is kinetically controlled. The Ni/La₂O₃ catalyst is first exposed to CH₄/CO₂ mixture at 750°C until the reaction rate reaches the stable level (cp. Fig. 1). After this, the reaction rates obtained at 550, 650 and 750°C are monitored as a function of time on stream (Fig. 2). It is shown that, after the above treatment, the resultant Ni/La₂O₃ catalyst does not exhibit any deactivation during 20 hours of reaction at 550, 650 and 750°C. These results are of significance since it is known that even supported noble metal catalysts, e.g. Rh catalyst, which has been reported to be the best catalyst for carbon dioxide reforming of methane [Richardson and Paripatyadar, above, and Ashcroft, Cheetham, Green, Vernon, above], still suffers carbon deposition and deactivation at reaction temperatures below 700°C. The absence of catalyst deactivation over Ni/La₂O₃ catalyst in a wide temperature range (550 - 750°C) indicates that a new type of nickel compound is formed on the surface, following the exposure of the catalyst to the reaction mixture for 2 to 5 hours.

Example 4

In this example, the long-term (100 hours of reaction) stability of a 17 wt% Ni/La₂O₃ was investigated at 750°C under integral reaction conditions (i.e. high methane conversions). A reaction contact time which keeps the conversions somewhat lower than those expected at thermodynamic equilibrium was used. This allows to study the catalytic performance at high conversions, while catalyst deactivation, if there is any, can also be easily detected.

Fig.3 shows the alterations of conversion of methane and carbon dioxide, and selectivity to carbon monoxide and hydrogen as a function of time on stream. Both conversion and selectivity increase rapidly during the initial several hours of reaction. After this, the conversion and selectivity tend to be essentially invariable with time on stream during 100 hours of reaction. The weight of the used catalyst was found to be somewhat larger than that of the fresh one, suggesting that carbon species formed from the gas phase on the used catalyst surface. However, this carbon species must be at steady-state, which does not cause any catalyst deactivation, as is demonstrated in Fig. 3.

Example 5

This example describes the influence of nickel metal loading on the reaction rate and the stability of Ni/La₂O₃ catalyst. Fig.4 shows the influence of metal loading on the reaction rate (using units of mmol/g_{metal}/s) and the stability of Ni/La₂O₃ catalyst at 1023 K. It is found that the catalyst with a low metal loading exhibits higher reaction rate, as compared to the one with higher metal loading. However, the Ni/La₂O₃ with low metal loading (e.g.3 wt%) exhibits catalyst deactivation with time on stream, being inferior to the Ni/La₂O₃ catalyst with high metal loading, over which no detectable catalyst deactivation is observed. Note that, although the Ni/La₂O₃ catalyst with low metal loading exhibits deactivation, its stability is still superior to those of Ni/ γ -Al₂O₃ and Ni/CaO catalysts.

Example 6

This example describes the effect of contact time on conversion over a 17 wt% Ni/La₂O₃ catalyst, and the effect of reaction temperature on conversion obtained at a contact time of 0.06 g.s/ml.

The reaction feed consisted of 20 vol.% CH₄, 20 vol.% CO₂ and 60 vol.% He. The alteration of contact time was realized by adjusting the amount of catalyst (10 - 50 mg) and the flow rate (25 - 300 mL/min). Fig.5 shows the effect of contact time on conversion over Ni/La₂O₃ catalyst at 1023 K. The conversions of methane and carbon dioxide increase rapidly as contact time increases from 0.002 to 0.07 g.s/ml. Conversions approaching those expected at thermodynamic equilibrium (i.e. the dotted lines) are already achieved at a contact time as low as ca. 0.06 g.s/ml, which corresponds to a superficial contact time of ca 0.02 seconds. The conversion obtained at a contact time of 0.06 g.s/ml was also studied at various temperatures (Fig. 6). It is observed that the conversions obtained at various temperatures are already equal to those expected at thermodynamic equilibrium (i.e. the dotted lines) at this contact time. Note that steam reforming of methane reactors over the commercial K-promoted Ni/ γ -Al₂O₃ catalyst typically have superficial contact times of the order of 1 second [M.V.Twigg, Catalyst Handbook, above]. The low contact time (ca. 0.02 seconds) required to obtain the equilibrium conversions of carbon dioxide reforming of methane over Ni/La₂O₃ catalyst indicates that the activity of Ni/La₂O₃ catalyst is high enough for industrial operation.

Example 7

In this example, the influence of various pretreatments (before the reaction) and treatments (after the reaction rate reaches the stable level) on the catalytic behaviour of Ni/La₂O₃ catalyst is described.

The influence of various pretreatment, i.e. Experiments No. 1-9, on the catalytic performance of Ni/La₂O₃ catalyst is shown in the following Table 2.

Table 2

Influence of pretreatment of 17 wt% Ni/La ₂ O ₃ on the reaction rates at initial and stable levels.			
Experiment No.	Pretreatments	Rate for CO formation (mmol/g.s)	
		Initial	Stable
1.	No treatment	0.13	1.91
2.	CO ₂ , 1023 K, 2h	0.07	1.44
3.	O ₂ , 1023 K, 2h	0.34	1.76
4.	CH ₄ , 1023 K, 1h	1.23	1.42
5.	H ₂ , 1023 K, 2h	0.94	2.10
6.	H ₂ , 1023 K, 5h	1.10	1.90
7.	H ₂ , 1023 K, 12h	0.67	2.00
8.	Air, 1123 K 10h	0.19	1.71
9.	Air, 1123 K, 10h then H ₂ , 1023 K, 2h	0.40	1.60

* Reaction conditions: P_{CH₄}=0.2 bar, P_{tot}=1.0 bar, CH₄/CO₂=1, W/F=2x10⁻³ g.s/ml.

It is noted that regardless of what kind of pretreatment is applied, the initial reaction rate is always lower than the reaction rate at the stable level. Although the pretreatment affects the initial rate to a significant extend, it does not influence significantly the reaction rate at the stable level. These results imply that there exists a strong tendency for Ni/La₂O₃ catalyst to form a stable surface structure under the working reaction conditions. It can also be derived that none of these pretreatments (see Table 2) resulted in an initial surface state which is similar to the stable surface state. Specifically, the results from Experiments No. 2, 5, 6, 7 suggest that the stable surface state of Ni/La₂O₃ is very different from metallic Ni or NiO supported on La₂O₃. The pretreatments of Experiments No. 8 and 9 are expected to facilitate the solid reaction between La₂O₃ and NiO, which presumably leads to formation of LaNiO₃ and/or La₂NiO₄ to a larger extent [J.L.G. Fierro, J.M.D. Tascon and L.G. Tejuca, J.Catal. 93 (1985) 83; N.Gunasekaran, A. Meenakshisundaram and V.Srinivasan, Indian J.Chem., Sect.A.21 (1982) 346]. The results indicate that neither the formation of LaNiO₃ nor La₂NiO₄ can account for the stable surface state. It appears that the stable surface structure consists of a mixture of several components involving nickel (and/or nickel oxide), lanthanum oxide, as well as the species from the gaseous phase, which are in "equilibrium" under the working reaction conditions.

Fig 7 shows the influence of several treatments on the reaction rate over Ni/La₂O₃ catalyst, following the establishment of the stable surface state. It is interesting to note that the stable surface structure is insensitive to exposure to air at room temperature, whereas a treatment at the reaction temperature in H₂ or O₂ flow alter or destroy the stable surface structure. However, it is shown that the stable surface structure is essentially retrievable after re-exposing the catalyst to the reaction mixture at the reaction temperature. This observation reveals that the catalyst can be easily regenerated, by exposure to H₂ or air, if it is deactivated.

Claims

1. A novel nickel-based catalyst with excellent activity and stability for carbon dioxide reforming of natural gas (methane) to synthesis gas, consisting of nickel in contact with La₂O₃ either in the form of nickel supported on La₂O₃ carrier or in the form of nickel on La₂O₃ particles dispersed on a conventional carrier such as γ -Al₂O₃, e.g. by techniques of wet-impregnation or others, characterized in that a new surface structure is formed during the initial 2-5 hours of reaction time during which period a significant increase in reaction rate is performed, after which the new surface composition and structure of the new Ni/La₂O₃ catalyst becomes excellently stable exhibiting no deactivation over long term reaction in the temperature range of 550 - 800°C by showing good resistance to coke formation, achieving near complete conversion of methane and carbon dioxide, and around 100% selectivity to carbon monoxide and hydrogen at about 800°C and superficial contact time of ca. 0.02 seconds.
2. A catalyst in accordance with claim 1, consisting of Ni in contact with La₂O₃.
3. A catalyst as in claim 1, where nickel nitrate is used as nickel metal precursor.
4. A catalyst as in claim 1 where other nickel compound, e.g. nickel oxide, nickel carbonate, nickel chloride, etc., is used as nickel metal precursor.
5. A catalyst as in claims 1 - 4, where La₂O₃ is used as a support.
6. A catalyst as in claims 1 - 5, where the lanthanum compound other than lanthanum oxide, e.g. lanthanum nitrate, lanthanum hydroxide, lanthanum carbonate, etc., is used as the La₂O₃ precursor.
7. A catalyst for carbon dioxide reforming of natural gas (methane) to synthesis gas, in accordance with any one of claims 1-6, containing more than one of the following compounds: Ni, NiO, La₂O₃, La₂O₂CO₃, La₂(CO₃)₃, NiCO₃, NiLa₂O₄, LaNi₅, LaNiO₃, La₂NiO₄, all of which are possibly formed from Ni/La₂O₃ pairs under working reaction conditions.

8. A catalyst as in claims 1 - 7, where the active nickel compound resulted from the interaction between species in the gas phase under working conditions and nickel metal and/or nickel oxide, e.g. nickel carbide, is additionally present.
- 5 9. A catalyst as in claim 1 - 8, where the lanthanum compound resulted from the interaction between species in gas phase under working conditions and lanthanum oxide is additionally present.
- 10 10. A method for the preparation of the catalysts claimed in claims 1 - 9, consisting of wet-impregnation technique which results in the catalyst containing nickel crystallites and La_2O_3 , characterized in that La_2O_3 is impregnated with an aqueous solution containing the desired amount of nickel nitrate, evaporating the water, drying, grinding, sieving and heating under N_2 flow until complete decomposition of nickel nitrate and reducing the catalyst at 500°C in H_2 flow for at least 5 hours and at 750°C in H_2 flow for 2 hours, thus achieving a ca. 1% dispersion for a 17 wt% Ni/ La_2O_3 catalyst.
- 15 11. The use of the catalysts in accordance with claims 1-9, in a reaction consisting of carbon dioxide reforming of hydrocarbon(s) other than methane (e.g. low alkane hydrocarbons, aromatic hydrocarbons) to synthesis gas and other products.
- 20 12. The use of the catalysts according to claims 1-9 in reactions using the catalysts according to claims 1-9, consisting of steam reforming of natural gas (methane) to synthesis gas.
- 25 13. The use of the catalysts according to claims 1-9 in reactions using these catalysts consisting of partial oxidation of methane to synthesis.
- 30 14. The use of the catalyst according to claims 1-9 and 11-13 in any type of reactor which is employed industrially for said processes, e.g. fixed bed reactor, fluid bed reactor, monolythic-type reactor, etc. for carbon dioxide reforming of methane and/or natural gas or hydrocarbons to synthesis gas or other products.
